Outline

- Motivation
- Model Synthesis Problem
 - Decomposition
 - Types of problems
 - Challenges
- Model Synthesis using
 - Linear Programming
 - Genetic Programming
 - Decision trees
 - Evolutionary Strategy
 - Local Search

Motivation: a use case

- Consider a real-world business process, e.g.,
 - Manufacturing of a product
 - Delivery of goods
- Goal #1: Simulation, e.g.,
 - To estimate operating costs
 - To estimate production volume
- Goal #2: Optimization, e.g.,
 - To minimize operating costs
 - To maximize production volume
- To achieve these goals one needs a mathematical model of the business process

A Mathematical Programming (MP) Model

- Variables
 - Represent the input, output and parameters of the business process
 - Specified with domains: Real, Integer, Binary etc.
- Objective function
 - The goal to achieve
- Constraints
 - Specify relationships between variables, e.g., operating conditions
 - Manual construction is time-consuming:
 - Requires deep insight into the business process
 - Requires transformation to form accepted by a solver, e.g., linear
 - Humans are error-prone and errors in constraints are expensive
- Simulation and optimization achieved using solvers, e.g.,

MODEL SYNTHESIS PROBLEM

General Model Synthesis Problem

• Input:

- Examples of states (values of variables)
 - Acquired by e.g., recording operations of the process
- A class of MP model to synthesize
 - E.g., Linear Programming, Quadratic Programming, etc.
- Output:
 - An objective function representing the outcome of the business process
 - A set of constraints comply with the examples

This is a classification problem

This is a regression problem

Problem decomposition

- The syntheses of an objective function and the constraints are largely independent
- The constraints define what is the feasible solution, and the objective function assesses the quality of this solution
- A single set of constraints can made up an MP model with an arbitrary objective function:
 - It does not matter for the constraints whether an objective function calculates a time cost, monetary profit, or waste of a material
- The synthesis of the objective function as a regression against a specific variable of the problem has many existing solutions
- The synthesis of the constraints surprisingly gained only a little attention in the state-of-the-art works

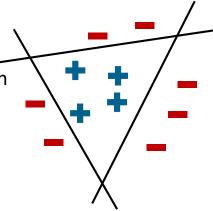

The remaining of this presentation is on constraint synthesis

Two-Class Constraint Synthesis Problem (2-CSP)

- Input:
 - Set X of examples x labeled as
 - Feasible represent the states reached during normal execution
 - Infeasible erroneous, faulty or undesired states
 - A class of constraints to synthesize
 - E.g., linear, quadratic, etc.
- Output:
 - A set C of constraints in the form of

p(x) ≤ a

- Where p(x) is a function of the given class and a is a constant
- Such that
 - The number of feasible examples satisfying all constraints in C is maximized (true positives)
 - The number of infeasible examples violating at least one constraint in C is maximized (true negatives)

2-CSP is NP-hard

- The problem of determining whether two sets of examples are separable using a fixed number of k ≥ 2 linear constraints is NPcomplete [1].
- It is NP-complete even if k is not fixed but bounded by the square of the number of dimensions n, i.e., $2 \le k \le n^2$ [2].
- In consequence, synthesizing $k \ge 2$ linear constraints, where k is either fixed or bounded by n^2 , is NP-hard.
- The complexity of learning $k \ge 2$ non-linear constraints is an open question.

[1] Nimrod Megiddo, "On the complexity of polyhedral separability", Discrete & Computational Geometry 3, 4 (1988), pp. 325 – 337.

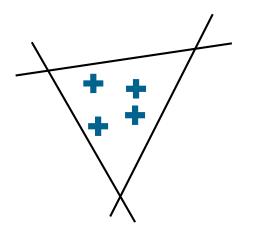

[2] Avrim L. Blum and Ronald L. Rivest, "Training a 3-node neural network is NP-complete", *Neural Networks* 5, 1 (1992), pp. 117 – 127.

One-Class Constraint Synthesis Problem (1-CSP)

- Input:
 - Set X of examples x
 - No labels
 - The examples are assumed to represent feasible states
 - A class of constraints to synthesize
 - E.g., linear, quadratic, etc.
- Output:
 - A set C of constraints in the form of

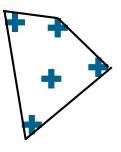

p(x) ≤ a

- Where p(x) is a function of the given class and a is a constant
- Such that
 - The number of feasible examples satisfying all constraints in C is maximized (true positives)
 - The margin of the constraints to the closest examples is minimized

Properties of 1-CSP

- This is a one-class classification problem
- Time-complexity of 1-CSP for $k \ge 2$ constrains is an open question
- Assuming linear constraints, the convex hull co(X) is the optimal solution, because:
 - All examples from X are included in co(X),
 - The margin is 0 for all constraints, as the examples are the vertexes of co(X)

- The number of facets of a convex hull grows exponentially with dimensionality n, and so the time of calculating co(X)
 - Unfortunately, I have no formal proof for time-complexity w.r.t. n.

Convex hull is not the best solution when generalization is under consideration

- An optimal solution of an LP model made of
 - Convex hull-based constraints
 - Any linear objective function

is an example from the training set X

- Hence:
 - Optimization of a convex hull-based LP model is futile
 - We cannot find a solution that we have not known before
 - Also, it is often more efficient to enumerate the known solutions from X than actually solving an LP model with a large number of constraints
- In general:
 - Too tight constraints limit generalization and may cause an optimal solution to be suboptimal in practice
 - Too loose constraints are detrimental too, as they may allow for solutions that happen inapplicable in practice

The curse of dimensionality

- Assume that:
 - The optimal solution is a constraint resembling an n-ball centered in \mathbf{y} with radius r and volume $V \sqcup r^n$
 - An algorithm produces a constraint resembling an n-ball centered in **y**, but commits an error in the radius by extending it by infinitely small $\P r > 0$
- Then:
 - The volume of the synthesized n-ball is $V ext{ for } (r + \partial r)^n$
 - It is exponentially with n greater than the volume of the optimal n-ball

$$\frac{V \Box}{V} \propto \left[1 + \frac{\partial r}{r} \right]^n \quad \text{and} \quad \lim_{n \to \Box} \frac{V \Box}{V} = \Box$$

- The volume of the margin between the n-balls grows exponentially with n
- In high dimensions, an apparently negligible error in a constraint may cause dramatic deterioration of virtually any data-set-backed performance measure for this constraint, as the margin between it and the optimal constraint may include exponential number of examples

Synthetic performance assessment

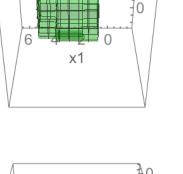

- Synthetic benchmarks MP models with parameters:
 - n number of variables
 - k number of alternative subsets of constraints
- Training sets
 - 1-CSP: Feasible examples uniformly sampled from feasible region of an MP model
 - 2-CSP: Feasible and infeasible examples uniformly sampled from the Cartesian product of domains of variables
- Test sets
 - Feasible and infeasible examples uniformly sampled from the Cartesian product of domains of variables
- Data-based measures of fidelity
 - E.g., accuracy, F₁-score,...
- Syntactic measures of fidelity
 - E.g., angles between the corresponding constraints in the synthesized and the benchmark MP models

Examples of benchmarks

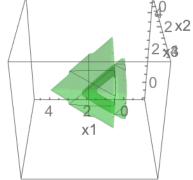

$$\begin{array}{ll} \forall_{j=1}^{k} \forall_{i=1}^{n} : x_{i} - Lb_{j} &\geq ij - L \\ \forall_{j=1}^{k} \forall_{i=1}^{n} : x_{i} + Lb_{j} &\leq ij + id + L \\ & \sum_{j=1}^{k} b_{j} &\geq 1 \\ \forall_{i=1}^{n} : x_{i} \in [i - ikd, i + 2ikd] \\ \forall_{j=1}^{k} : b_{j} \in \{0, 1\} \end{array}$$

Simplex^{*k*}_{*n*}:

$$\begin{array}{ll} \forall_{j=1}^{k} \forall_{i=1}^{n} \forall_{l=i+1}^{n} : x_{i} \cot \frac{\pi}{12} - x_{l} \tan \frac{\pi}{12} - Lb_{j} & \geq 2j - 2 - L \\ \forall_{j=1}^{k} \forall_{i=1}^{n} \forall_{l=i+1}^{n} : x_{l} \cot \frac{\pi}{12} - x_{i} \tan \frac{\pi}{12} - Lb_{j} & \geq 2j - 2 - L \\ \forall_{j=1}^{k} : \sum_{i=1}^{n} x_{i} + Lb_{j} & \leq jd + L \\ & \sum_{j=1}^{k} b_{j} & \geq 1 \\ & \forall_{i=1}^{n} : x_{i} \in & [-1, 2k + d] \\ & \forall_{j=1}^{k} : b_{j} \in & \{0, 1\} \end{array}$$

5x2

 Ball_n^k :

d is a parameter = 2.7

$$\begin{aligned} \forall_{j=1}^{k} \sum_{i=1}^{n} \left(x_{i} - i - \frac{2\sqrt{6}(j-1)d}{i\pi} \right)^{2} + Lb_{j} &\leq d^{2} + L \\ \sum_{j=1}^{k} b_{j} &\geq 1 \\ \forall_{i=1}^{n} : x_{i} \in \left[i - 2d, i + \frac{2\sqrt{6}(k-1)d}{\pi} + 2d \right] \\ \forall_{j=1}^{k} : b_{j} \in \{0, 1\} \end{aligned}$$
where:
L is a big constant

Performance assessment on real-world problems

- Let there be a data set of states achieved by a business process
- General workflow consists of four steps:
 - 1. Synthesize a set of constraints from the data set
 - 2. Attach an objective function
 - A regression model calculated using the data set, or
 - A known objective function
 - 3. Optimize the MP model
 - 4. Validate the optimal solution with the data set
 - E.g., assess similarity to the one or more most similar examples

Challenges for assessing an MP model for a real-world business process

- 1-CSP:
 - The data set consists of feasible examples only
 - False positives and True negatives are 0 for any MP model
 - So, most of the performance measures typical to Machine Learning are biased or cannot be calculated
- 1-CSP & 2-CSP:
 - The optimal solution of an MP model usually lies on a constraint
 - In particular, this holds for all Linear Programming models
 - In statistical sense, the optimal solution is an outlier it lies on the boundary of a distribution of feasible solutions
 - From the optimization point of view, there is no reason to reward the MP model for the interior of its feasible region; only the boundary matters
 - Hence, assessment of an MP model using a test set is futile:
 - The test set-based measures (usually) reward the MP model equally for each example
 - The test set is a sample of the space that may be far from the boundary of the feasible region
- 2-CSP:
 - The data set is often imbalanced, as infeasible states like errors and faults are avoided
- The actual MP model is unknown
 - We are unable to calculate syntactic measures of fidelity

ALGORITHMS

Solving 2-CSP using Mixed-Integer Linear Programming (MILP)

- The general idea is to encode the 2-CSP using a MILP problem and solving optimally
- Ockham's razor:
 - The objective is to find the minimal set of constraints that separate the sets of feasible and infeasible examples
 - Misclassification is disallowed
- The algorithm synthesizes LP models and user-defined classes of NLP models

411.4 144.0

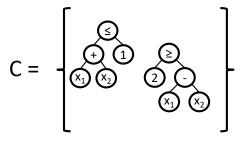

Conclusions

- Solving a MILP problem is NP-hard and so we had to terminate solver prematurely for large problem instances
- The algorithm overfits and is susceptible to noise
 - The MILP problem is aimed at minimizing model complexity while guarantying separation of the feasible and the infeasible examples
- The feasible region is often overestimated
 - The algorithm strives to use as simple constraints as possible and in the effect the feasible region features many outlying vertexes
- The training set is typically imbalanced with higher share of the feasible examples, while the algorithm requires higher share of the infeasible examples to avoid overestimating the feasible region

GENETICS: Genetic Programming Constraint Synthesis for 2-CSP

- Representation
 - An individual C is a set of constraints
 - A constraint is an Abstract Syntax Tree (AST)
- Strongly-typed Genetic Programming
 - Tree root is one of \leq , =, \geq
 - ≤, =, ≥ accept any other instructions as arguments
- Instruction sets
 - For Linear Programming models:
 - +, -, ×, x_i, 1, ERC where × is multiplication that accepts +, -, 1, ERC as its left-hand argument
 - For polynomial models:
 - +, -, ×, *, x², x_i, 1, ERC where * accepts all instructions as arguments

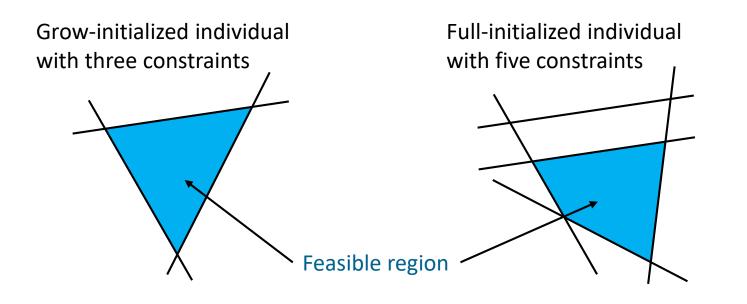

Tomasz P. Pawlak, Krzysztof Krawiec, Synthesis of Mathematical Programming Constraints with Genetic Programming, EuroGP 2017, Lecture Notes in Computer Science 10196:178-193, Springer, 2017.

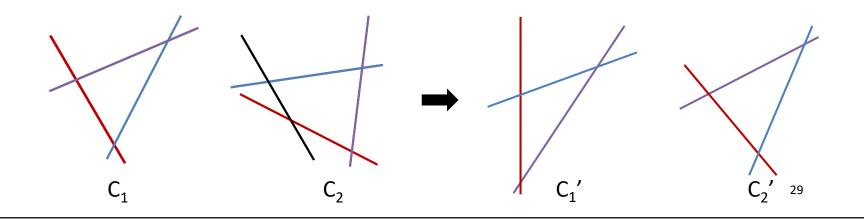

GENETICS: Fitness function

- Assessment of C on example x is:
 - For a feasible example **x**:
 - The number of constraints in C violated on **x**
 - For an infeasible example **x**:
 - 1 if all constraints in C are met for x, 0 otherwise
- Parsimony pressure tests
 - Minimize the number of constraints in C
 - Minimize the total number of nodes in constraints in C
- Assessment of C is a vector of assessments on examples and parsimony pressure tests
 - Lexicase selection runs on these vectors
- The best-of-run individual C minimizes a sum of vector elements

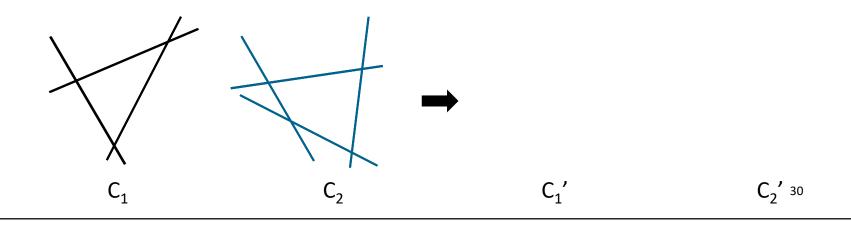

- Ramped Half-and-Half (RHH) initialization
 - Grow and Full build individual constraints
 - Total number of constraints initialized in C is parameterized:
 - Grow draws it from the parameterized range
 - Full uses the maximum in that range

- Constraint Tree Crossover (CTX)
 - Draws one constraint from each parent C₁ and C₂
 - Runs Tree Swapping Crossover and inserts crossed-over constraints into corresponding offspring $C_1^{'}$ and $C_2^{'}$
- Constraint Tree Mutation (CTM)
 - Initializes a random individual C_r using RHH
 - Runs CTX for the given parent C and C_r and returns one of resulting offspring

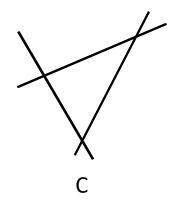

- Constraint Swapping Crossover (CSX)
 - Given two parents C₁ and C₂, their constraints are randomly assigned to two offspring C₁['] and C₂[']
- Constraint Swapping Mutation (CSM)
 - Initializes a random individual C_r using RHH
 - Runs CSX for the given parent C and C_r and returns one of resulting offspring

• Gaussian Constant Mutation (GCM)

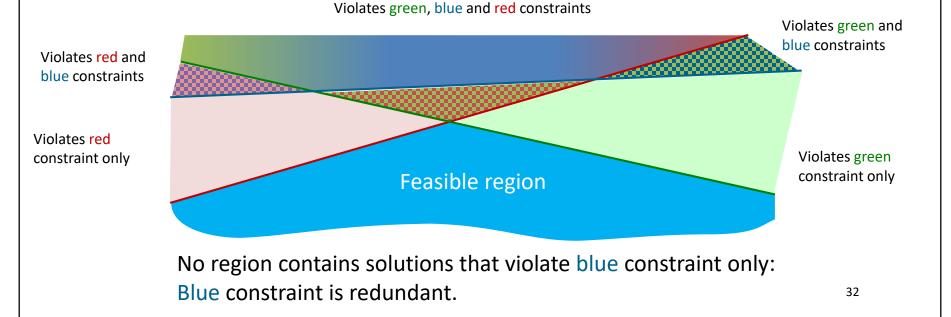

- Draws a constant c from each constraint in the given parent C
- Replaces c with c'~N(c, 1)

C'

GENETICS: Post-processing

- Remove redundant constraints from the best-or-run individual:
 - A constraint is redundant if for all solutions it is either satisfied or another violated constraint exists

Mean Jaccard index of the feasible regions of the synthesized and the actual MP models

GENETICS: Conclusions

- The test-set results are better than for MILP-based method
- GENETICS still overestimates the feasible region
- Synthesized constraints have different syntax than the actual ones
 - GENETICS produces one out of many alternative models that fit training set
- Curse of dimensionality
 - When the number of variables becomes large GENETICS achieves worse results
 - Larger training set improves performance

Genetic One-Class Constraint Synthesis (GOCCS)

- An equivalent of GENETICS for 1-CSP
- Representation and operators are mostly the same
- The main differences consist of:
 - Validation set of unlabeled examples sampled prior to evolutionary run
 - The unlabeled examples are located from the known feasible examples
 - Two optimization criteria, both maximized:
 - The number of true positives
 - The number of true negatives
 - NSGA-II post-selection instead of Lexicase selection

Tomasz P. Pawlak, Krzysztof Krawiec, Synthesis of Constraints for Mathematical Programming with One-Class Genetic Programming, IEEE Transactions on Evolutionary Computation, IEEE Press, 2018. IF=10.629, 50p MNiSW

Mean angle between the corresponding constraints in the synthesized and the actual MP models

Modeling of Wine Quality

- Wine Quality data set [1]
 - 11 physiochemical attributes of wine
 - A quality assessment [0-10] calculated as the median of the assessments made by at least three sensory assessors
 - 1599 red wine examples, 4898 white wine examples
 - 1-CSP

·		Red wine					White wine				
Variable	Meaning	Min	Mean	Max	Domain	Min	Mean	Max	Domain

Percentile in	dataset		99%		86%		79%

• Due to FSD > TSD in the optimal solution, we added extra constraints for the red wine model:

 $-FSD + TSD \ge 3$

 $\text{FSD} - 0.8571\text{TSD} \leq 0$

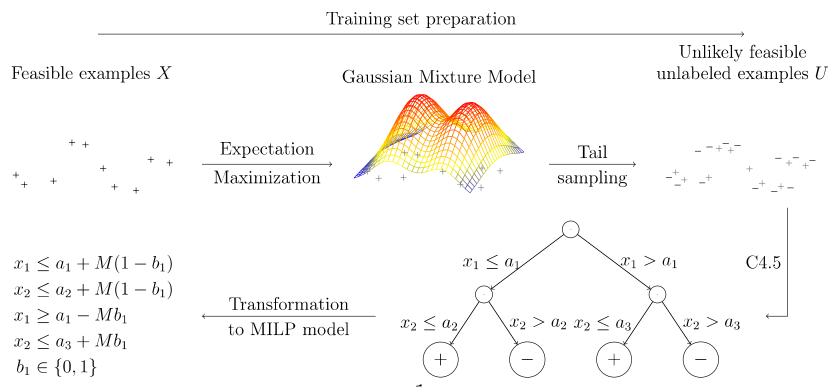

• They are based on the evidence in the data set that min TSD – FSD = 3 and max FSD/TSD = 0.8571

GOCCS: Conclusions

- GOCCS has good performance on low-dimensional 1-CSP
 - E.g., up to 6 7 variables
- GOCCS underestimates the feasible region
- GOCCS is susceptible to the curse of dimensionality
- The synthesized NLP models are oversize, however LP models have correct size

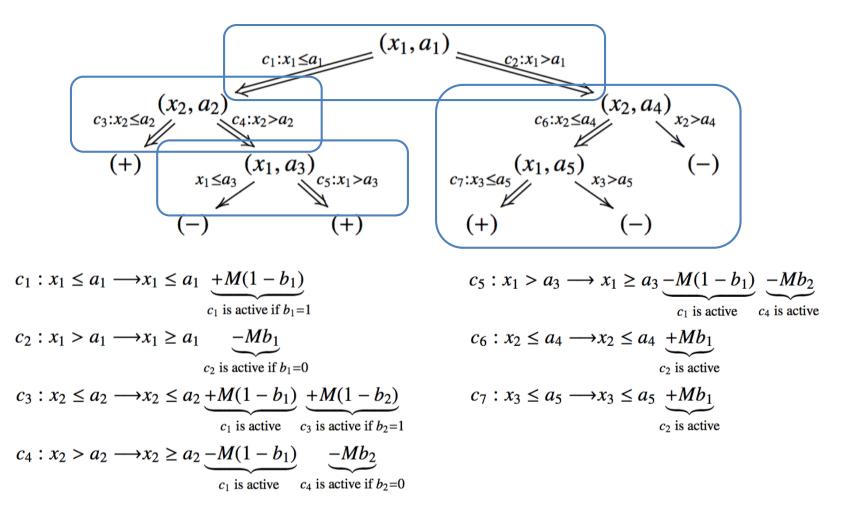

Constraint Synthesis with C4.5 (CSC4.5) for 1-CSP

• General idea: Build a decision tree and transform it to a MILP model

 Patryk Kudła, Tomasz P. Pawlak, One-class synthesis of constraints for Mixed-Integer Linear Programming with C4.5 decision trees, Applied Soft Computing 68 (2018) 1-12. IF=3.541, 40p MNiSW

A decision tree is a MILP model

Modeling of Wine Quality

- The same Wine Quality data set
 - Divided into training set and test set in roughly 50%:50%
 - Test set supplemented with unlabeled likely infeasible examples
- Red wine MIQP model
 - 517 constraints
 - 171 auxiliary binary variables
 - Jaccard index of feasible region calculated on test set: 0.90
- White wine MIQP model
 - 1373 constraints
 - 484 auxiliary binary variables
 - Jaccard index of feasible region calculated on test set: 0.91

CSC4.5: Conclusions

- The synthesized MILP models may be non-convex w.r.t. the input variables
- The synthesized MILP models are oversize
- CSC4.5 is unable to model interactions between variables
- CSC4.5 is susceptible to the curse of dimensionality

Evolutionary Strategy-based One-Class Constraint Synthesis (ESOCCS) for 1-CSP

- General idea:
 - Model the distribution of the feasible states using Gaussian Mixture Model and Expectation Maximization
 - Sample the tail of that distribution for unlabeled and likely infeasible examples
 - Evolve a population of constraints using (μ + λ)-Evolutionary Strategy
 - Single-population cooperative co-evolution
 - Select a minimal subset of constraints from the population to produce an MP model

Tomasz P. Pawlak, Synthesis of Mathematical Programming models with one-class evolutionary strategies, Swarm and Evolutionary Computation, Elsevier, 2018 (in press). IF=3.893, 50p MNiSW

$(\mu+\lambda)$ -Evolutionary Strategy in a singlepopulation cooperative co-evolution mode

- Representation of a constraint:
 - Vector of weights w_i of predefined terms (e.g., variables)
 - A constant w₀
 - Vector of standard deviations σ_i corresponding to w_i
 - Vector of rotation angles α_{ij} corresponding to the pairs of w_i and w_j
- Population: a set of μ constraints
- Gaussian initialization $w_i \sim N(0,1)$

• Correlated mutation

$$\begin{aligned}
\forall_i : \sigma'_i \sim \sigma_i e^{\tau \cdot N} e^{\tau \cdot N(0,1)} & \text{Std. dev. mutation} \\
\forall_{ij} : \alpha'_{ij} \sim \beta \mathcal{N}(\alpha_{ij}, 1) & \text{Angles mutation} \\
\sum_{ij} = \begin{cases}
\sigma'^2_{ij} & i = j \\
\frac{1}{2} (\sigma'^2_i - \sigma'^2_j) \tan(2\alpha'_{ij}) & i > j \\
\frac{1}{2} (\sigma'^2_j - \sigma'^2_i) \tan(2\alpha'_{ji}) & i < j
\end{aligned}$$
Element of covariance matrix

$$w' \sim \mathcal{N}(w, \Sigma) & \text{Weights mutation,} \\
\forall_i : w'_i \sim \mathcal{U}(\{w^{(1)}_i, w^{(2)}_i\}) & \text{Discrete recombination of } w_i \\
\forall_i : \sigma'_i = \frac{1}{2} (\sigma^{(1)}_i + \sigma^{(2)}_i) & \text{Intermediate recombination of } \alpha_{ij}, \\
\end{aligned}$$

Constraint selection and fitness assessment

- Let P' be a constraint pool made of μ parent constraints and λ offspring constraints produced by the search operators
- Selection of the minimal subset of P' that maximize the number of correctly classified examples is a generalized set cover problem

$$\min \underbrace{\sum_{c_j \in P'}^{(a)} |X_{\overline{c_j}}| b_j}_{(a)} + \underbrace{\sum_{\mathbf{x}_k \in U}^{(b)} v_k}_{(b)} + \underbrace{0.0001 \sum_{c_j \in P'}^{(c)} b_j}_{(c)}$$
(1)

subject to

$$\forall \boldsymbol{x}_k \in U : \sum_{\substack{c_j \in P', \\ \neg c_j(\boldsymbol{x}_k)}} b_j + v_k \ge 1$$
(2)

• Where

 $\forall b_j, \forall v_j \in \{0, 1\},$

- (a) is the number of feasible examples violating the selected constraints
- (b) is the number of unlabeled examples satisfying the selected constraints
- (c) is the number of constraints
- This problem is solved optimally, thus the synthesized model is minimal
- The selected constraints are removed from P' and advance to the next generation population
- Constraint selection repeats until the next generation population is full 51

(a) Mean angle between the corresponding constraints(b) Jaccard index of the feasible regionsof the synthesized and the actual MP models

Modeling Rice Production

- Rice production in India data set [1]
 - Heavily preprocessed in this work
 - Variables in absolute units recalculated relatively to the farm area
 - Ordinal variables transformed into integers
 - Six output variables aggregated into two variables
 - 1022 examples of rice farms

	-			-

ESOCCS² – five improvements to ESOCCS

- I1: Estimation of distribution of feasible states using Kernel Density Estimation (KDE) instead of Expectation Maximization (EM)
 - The assumption that the actual distribution is a Gaussian Mixture may be false
 - KDE is non-parametric estimation method
 - It difficult to estimate bandwidth matrix for KDE and many approaches exist
 - We used Silverman's rule
- I2: Denser sampling of unlabeled examples
 - In ESOCCS the density of a sample of unlabeled examples decreases with dimensionality
 - ESOCCS² increases the sample size to reduce the decrease rate
- I3: Bounding-box initialization
 - The initial population is supplemented with bounding-box of the training set
- I4: Reuse of constraints in successively built models
 - The constraints are not removed from the pool, but use of some subsets of constraints together is forbidden
- I5: Prevention from degenerate empty models
 - Degenerated models are explicitly prohibited by new formulation of the generalized set cover problem

Tomasz P. Pawlak, Performance Improvements for Evolutionary Strategy-based One-Class Constraint Synthesis, GECCO'18, ACM, 2018.

ESOCCS vs ESOCCS²

- In total 23 combinations of I1 I4 applied to ESOCCS are verified
- The p-values of the Wilcoxon signed rank test for significance of differences in Jaccard indexes of the feasible regions for each of I1 – I4:

• ESOCCS with the combination of I2, I3, I4 is significantly better than bare ESOCCS and 16 other setups in LP models and 17 other setups in NLP models

ESOCCS: conclusions

- A fully configurable type of the synthesized model
- Good generalization performance and handling of noise
- Significant computation cost due to solving the set cover problem
- The curse of dimensionality is still an issue
- KDE (I1) failed probably due to inadequate algorithm for calculating bandwidth matrix

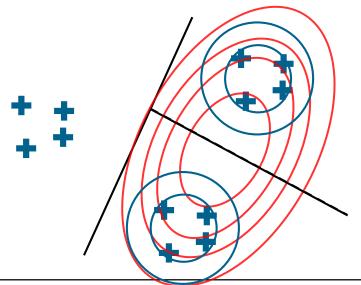

One-Class Constraint Acquisition with Local Search (OCCALS) for 1-CSP

- General idea:
 - Partition the training set using x-means
 - Find an LP model for each partition using local search
 - Remove redundant constraints in each LP model independently
 - Create a MILP model implementing alternative of the individual LP models

• Daniel Sroka, Tomasz P. Pawlak, One-Class Constraint Acquisition with Local Search, GECCO '18, ACM, 2018.

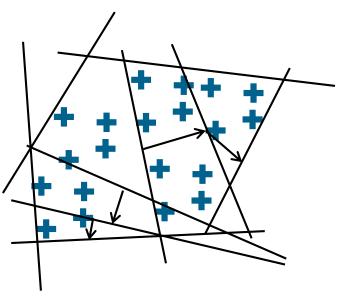

Training set partitioning using x-means

- Make an initial partitioning using k-means with a fixed k
 - E.g., k = 2
- Split each partition P_i further into P'_i and P''_i using k-means with k=2
- If $BIC(P'_i, P''_i) > BIC(P_i)$ then
 - Replace P_i with P'_i and P''_i
 - \bullet Repeat these steps for $P_i^{\,\prime}$ and $P_i^{\,\prime\prime}$
- BIC is Bayesian Information Criterion under Gaussian Mixture

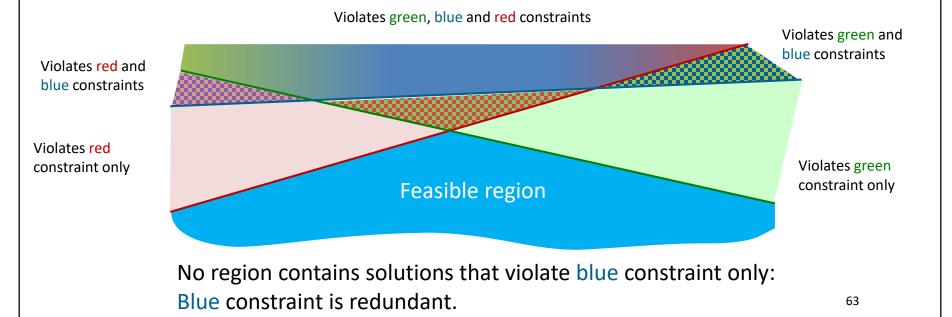

Local search of LP constraints

- For each partition c_{max} constraints are sought independently
- Local search finds one constraint at time
- The initial weights of a constraint are random
- Local search minimizes the number of false negatives
- Step size decreases with true positives

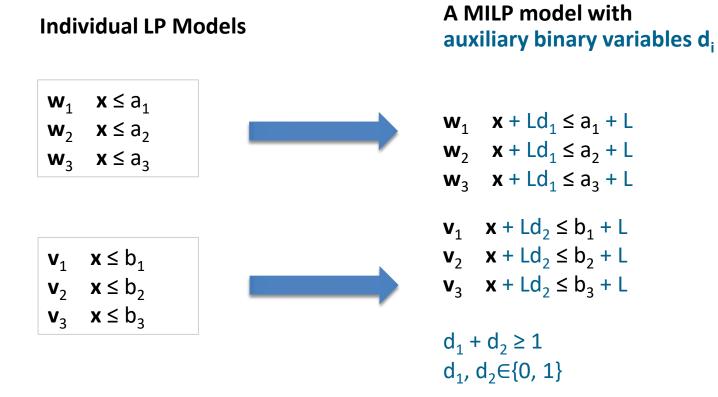

Removal of redundant constraints

• The same approach like in GENETICS is taken

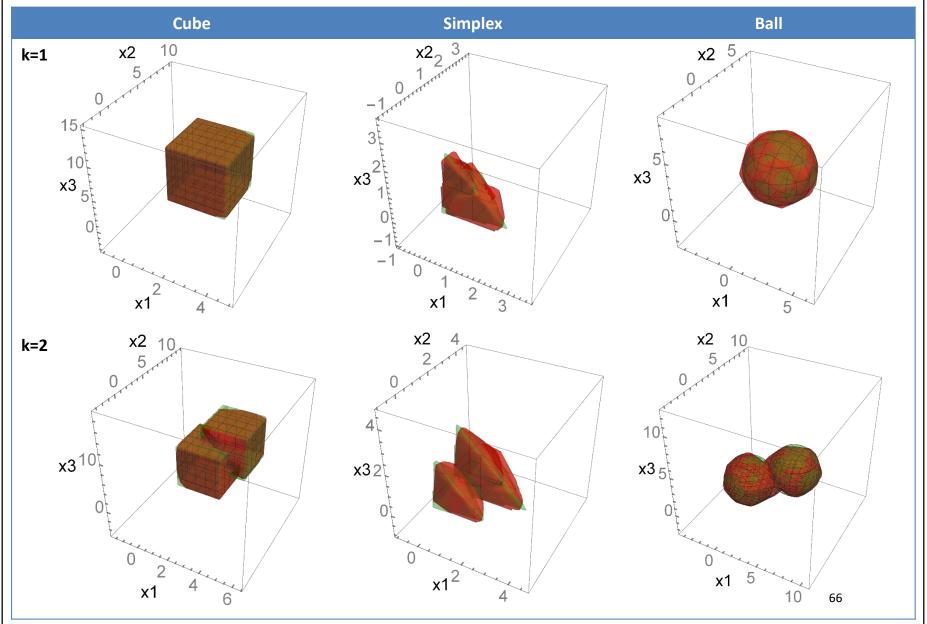

A MILP model implementing an alternative of LP models

L is a big constant

Visualization of the synthesized models

OCCALS: conclusions

- The most successful algorithm so far
- Quick and fast
- Good generalization performance and noise handling
- An improved version is under development

General conclusions

- Mathematical Programming (MP) is a common formalism for optimization methods, well-recognized both in business and academia
- Surprisingly, most of the MP models are handcrafted and the synthesis of MP models from data is underrepresented in literature
- We formally defined several variants of the synthesis problem, including 1-CSP and 2-CSP
- 2-CSP problem is known to be NP-hard
- 1-CSP is more practical due to no need for infeasible examples, but it is also more difficult to solve than 2-CSP
- We proposed several heuristic approaches to solve both 1-CSP and 2-CSP

Future research directions

- Drop requirement for second-class examples in some of the presented algorithms
- Design novel performance measures calculable using feasible examples only
- Design more objective experimental protocol for real-world data
